

Analyse harmonique et dernier théorème de Fermat

TOULEB Bashir

2023-2024

Théorème (Fermat-Wiles)

Il n'existe pas d'entiers strictement positifs x, y et z tels que $x^k + y^k = z^k$ dès que $k \geq 3$

Quand est-il des corps finis ?

Théorème (Fermat-Wiles)

Il n'existe pas d'entiers strictement positifs x, y et z tels que $x^k + y^k = z^k$ dès que $k \geq 3$

Quand est-il des corps finis ?

Théorème 0 (Babai)

Il existe $x, y, z \in \mathbb{F}_q^\times$ tel que $x^k + y^k = z^k$ dès que $q \geq k^4 + 4$

- 1 Analyse harmonique
- 2 Nombre de solutions
- 3 Intermède
- 4 Corps finis

On note G un groupe abélien fini de cardinal n .

Définition

$\widehat{G} = \text{Hom}(G, \mathbb{C}^*)$ est appelé le groupe dual de G .

Remarques

- $\widehat{G} = \text{Hom}(G, \mathbb{U})$
- $\widehat{\prod_{i=1}^r G_i} \simeq \prod_{i=1}^r \widehat{G}_i$ où G_1, \dots, G_n abéliens finis
- $r \geq 1, \bar{a} \mapsto (\chi_a : \bar{b} \mapsto e^{\frac{2i\pi}{r} ab})$ induit $\mathbb{Z}_r \simeq \widehat{\mathbb{Z}_r}$

Donc par théorème de structure des groupes abéliens finis (admis),

Théorème 1

G est isomorphe à $\widehat{\widehat{G}}$

Définition (algèbre de groupe)

- $L(G) = \mathbb{C}^G$.
- $(L(G), +, \times, \cdot)$ est une \mathbb{C} -algèbre de dimension n .
- $\langle f, g \rangle = \frac{1}{n} \sum_{a \in G} f(a) \overline{g(a)}$ est un produit scalaire sur $L(G)$.

Théorème 2

Les éléments de \widehat{G} forment une base orthonormée de $L(G)$.

Démonstration 2

Soit $\chi \in \widehat{G}$ tq $\chi \neq 1$. Donc $\exists b \in G$ tq $\chi(b) \neq 1$.

Or $S(\chi) = \sum_{a \in G} \chi(a) = \sum_{\theta \in G} \chi(b\theta) = \chi(b)S(\chi)$ donc $S = 0$.

Pour $\chi, \psi \in \widehat{G}$,

$$\langle \chi, \psi \rangle = \frac{1}{n} S(\chi \overline{\psi}) = \frac{1}{n} S(\chi \psi^{-1}) = \delta_{\chi, \psi}$$

Et $|\widehat{G}| = |G| = n = \dim L(G)$ donc c'est une BON.

Définition (transformée de Fourier)

À $f \in L(G)$ on associe $\widehat{f} \in L(\widehat{G})$ tel que $\widehat{f}(\chi) = n\langle f, \bar{\chi} \rangle = \sum_{a \in G} f(a)\chi(a)$.

Théorèmes (formule de Plancherel et inversion de Fourier)

Soit $f, g \in L(G)$

- $\langle \widehat{f}, \widehat{g} \rangle = n\langle f, g \rangle$
- $f = \frac{1}{n} \sum_{\chi \in \widehat{G}} \widehat{f}(\chi)\bar{\chi}$

Remarque

En notant δ l'indicatrice de $\{0\}$ il suit que

$$\widehat{\delta} = 1$$

$$\delta = \frac{1}{n} \sum_{\chi \in \widehat{G}} \chi$$

Théorème 3

Soit $A_1, \dots, A_m \subset G$ d'indicatrices $(1_{A_i})_{1 \leq i \leq m}$.

Le nombre \mathfrak{N} de solutions de l'équation $x_1 + \dots + x_m = 0$ ($x_i \in A_i$, $1 \leq i \leq m$) est

$$\mathfrak{N} = \frac{|A_1| \dots |A_m|}{n} + \frac{1}{n} \sum_{\chi \in \widehat{G} \setminus \{1\}} \prod_{i=1}^m \widehat{1}_{A_i}(\chi)$$

Démonstration 3

$$\begin{aligned} \mathfrak{N} &= \sum_{x_1 \in A_1, \dots, x_m \in A_m} \delta(x_1 + \dots + x_m) = \sum_{x_1 \in A_1, \dots, x_m \in A_m} \frac{1}{n} \sum_{\chi \in \widehat{G}} \chi(x_1 + \dots + x_m) = \\ &= \frac{1}{n} \sum_{\chi \in \widehat{G}} \left(\sum_{x_1 \in A_1} \chi(x_1) \right) \dots \left(\sum_{x_m \in A_m} \chi(x_m) \right) = \\ &= \frac{1}{n} \sum_{\chi \in \widehat{G}} \left(\sum_{x_1 \in G} 1_{A_1}(x_1) \chi(x_1) \right) \dots \left(\sum_{x_m \in G} 1_{A_m}(x_m) \chi(x_m) \right) = \\ &= \frac{1}{n} \sum_{\chi \in \widehat{G}} \prod_{i=1}^m \widehat{1}_{A_i}(\chi) \end{aligned}$$

Soit $A \subset G$

Définition

On définit $\phi(A) = \max_{\chi \in \widehat{G} \setminus 1} \{|\widehat{1}_A(\chi)|\}$

Théorème 4

Lorsque $m = 3$ on a,

$$\Delta = \left| \eta - \frac{|A_1||A_2||A_3|}{n} \right| < \phi(A_3) \sqrt{|A_1||A_2|}$$

Démonstration 4

Par le théorème 3 et l'inégalité triangulaire,

$$\Delta \leq \frac{1}{n} \sum_{x \in \widehat{G} \setminus \{1\}} |\widehat{1}_{A_1}(x)| |\widehat{1}_{A_2}(x)| |\widehat{1}_{A_3}(x)| \leq \frac{\phi(A_3)}{n} \sum_{x \in \widehat{G}} |\widehat{1}_{A_1}(x)| |\widehat{1}_{A_2}(x)|$$

Par inégalité de Cauchy-Schwartz,

$$\Delta \leq \frac{\phi(A_3)}{n} \sqrt{\sum_{x \in \widehat{G}} |\widehat{1}_{A_1}(x)|^2} \sqrt{\sum_{x \in \widehat{G}} |\widehat{1}_{A_2}(x)|^2} = \frac{\phi(A_3)}{n} \|\widehat{1}_{A_1}\| \cdot \|\widehat{1}_{A_2}\|$$

Par la formule de Parseval, $\Delta \leq \phi(A_3) \|1_{A_1}\| \cdot \|1_{A_2}\| = \phi(A_3) \sqrt{|A_1||A_2|}$

Bilan !

On souhaite majorer $\phi(A_3)$ dans $G = \mathbb{F}_q$ lorsque $A_1 = A_2 = A_3 = H(q, k)$ où

$$H(q, k) = \left\{ a^k, a \in \mathbb{F}_q^\times \right\}$$

afin d'obtenir $\mathfrak{N} > 0$

Définitions

- $\mathfrak{N}(q, k) = \mathfrak{N}$ dans \mathbb{F}_q pour $k \geq 3$ donné
- $\mathfrak{S}(q, k) = \left| \left\{ (x, y, z) \in \mathbb{F}_q^\times, x^k + y^k = z^k \right\} / \sim \right|$
- $\mathfrak{D}(q, k) = \frac{2\mathfrak{S}(q, k)}{q(q-1)^2}$

Remarque

- $\mathfrak{N}(q, k) = \left| \left\{ (x, y, z) \in H(q, k), x + y = z \right\} \right|$
- En général $\mathfrak{N}(q, k) \neq \mathfrak{S}(q, k)$
- Mais $\mathfrak{N}(q, k) > 0$ si et seulement si $\mathfrak{S}(q, k) > 0$

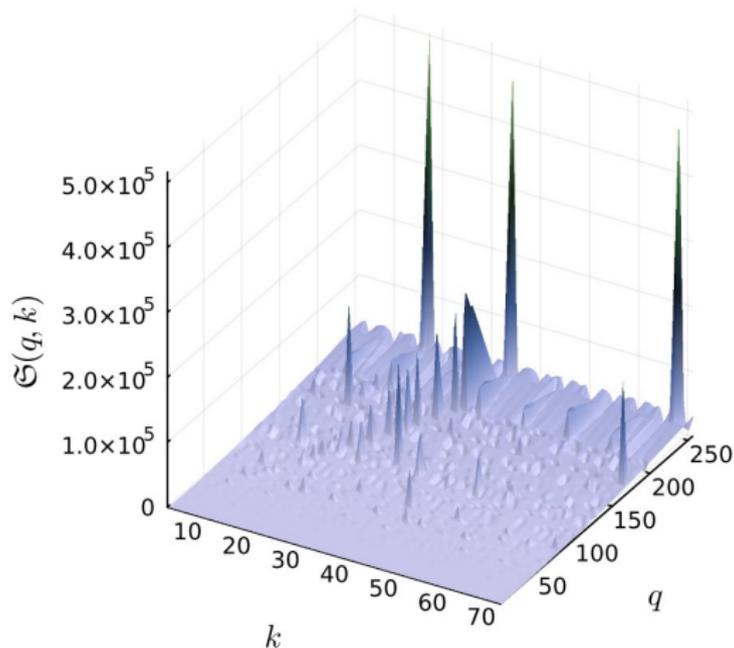

Figure: Nombre $\mathfrak{S}(q, k)$ de solutions non triviales de $x^k + y^k = z^k$ dans \mathbb{F}_q .

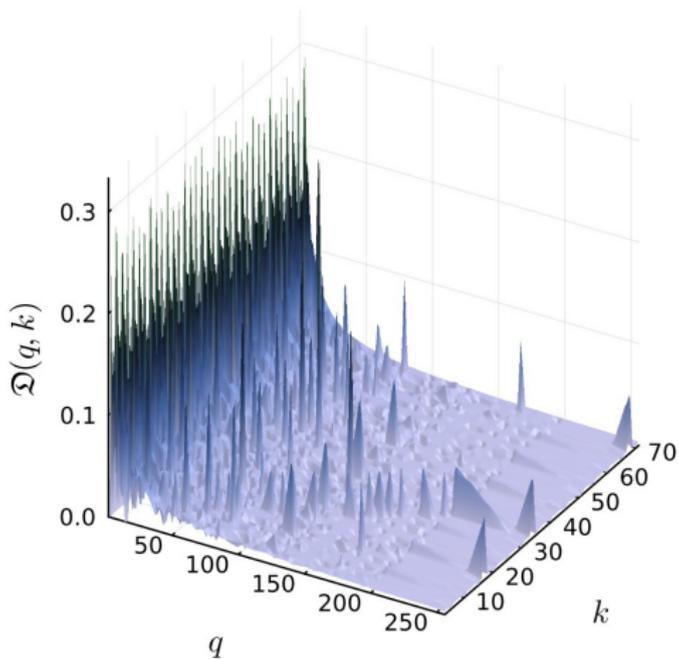

Figure: Densité $\mathcal{D}(q, k)$ en solutions non triviales de $x^k + y^k = z^k$ dans \mathbb{F}_q .

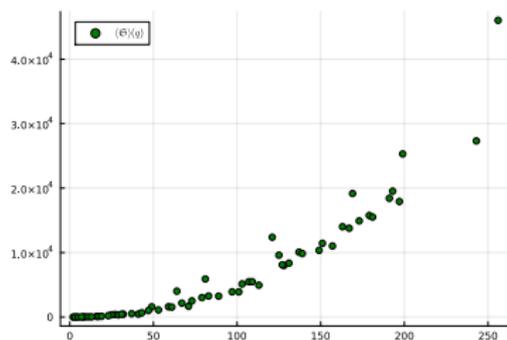

Figure: Nombre moyen $\langle \mathfrak{S} \rangle(q)$ de solutions

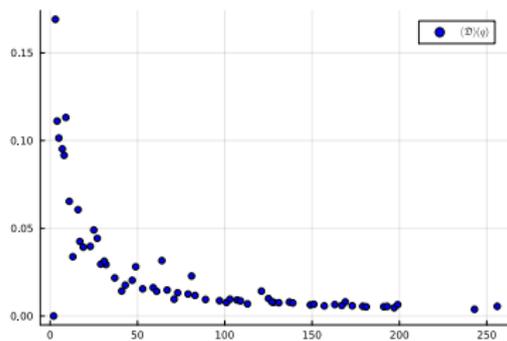

Figure: Densité moyenne $\langle \mathfrak{D} \rangle(q)$ en solutions

Définition (somme de Gauss)

Soit $\chi \in \widehat{\mathbb{F}_q}$, $\psi \in \widehat{\mathbb{F}_q^\times}$, on définit

$$G(\chi, \psi) = \sum_{a \in \mathbb{F}_q} \chi(a)\psi(a)$$

en posant $\psi(0) = 0$

Remarques

- $G(\chi_0, \psi_0) = q - 1$, où χ_0, ψ_0 sont triviaux
- $G(\chi_0, \psi) = 0$ si $\psi \neq \psi_0$
- $G(\chi, \psi_0) = -1$ si $\chi \neq \chi_0$

Théorème 5

Si $\chi \neq \chi_0$ et $\psi \neq \psi_0$ alors,

$$|G(\chi, \psi)| = \sqrt{q}$$

Démonstrations 5

On calcul,

$$|G(\chi, \psi)|^2 = G(\chi, \psi) \overline{G(\chi, \psi)} = \sum_{a \in \mathbb{F}_q^\times} \chi(a) \psi(a) \sum_{b \in \mathbb{F}_q^\times} \overline{\chi(b) \psi(b)} = \sum_{a, b \in \mathbb{F}_q^\times} \chi(a - b) \psi(ab^{-1}) = \sum_{a, c \in \mathbb{F}_q^\times} \chi(a(1 - c)) \psi(c)$$

donc,

$$|G(\chi, \psi)|^2 = \sum_{c \in \mathbb{F}_q^\times} \psi(c) \left(\sum_{a \in \mathbb{F}_q} \chi(a(1 - c)) - \chi(0) \right)$$

or $\sum_{a \in \mathbb{F}_q} \chi(a) = 0$ et $\sum_{a \in \mathbb{F}_q^\times} \psi(a) = 0$,

donc,

$$|G(\chi, \psi)|^2 = \psi(1)(q - 1) - \sum_{c \in \mathbb{F}_q^\times \setminus \{1\}} \psi(c) = (q - 1) - 0 + 1 = q$$

d'où $|G(\chi, \psi)| = \sqrt{q}$

On suppose dorénavant que $k|q-1$

Remarque (exercice 6.4)

$$|H(q, k)| = \frac{q-1}{k}$$

Résolution

$\Lambda : a \in \mathbb{F}_q^\times \mapsto a^k \in \mathbb{F}_q^\times$ est un morphisme donc $|\Lambda(\mathbb{F}_q^\times)| = |H(q, k)| = \frac{|\mathbb{F}_q^\times|}{|\ker \Lambda|}$.

soit $P = X^k - 1 \in \mathbb{F}_q[X]$, $P' = kX^{k-1} \neq 0$ donc P est à racines simples.

soit $\alpha \in \overline{\mathbb{F}_q}$ tel que $P(\alpha) = 0$.

or $\alpha^k = 1$ et $\exists n \in \mathbb{N} : q = nk + 1$ donc $\alpha^q = \alpha$ donc $\alpha \in \mathbb{F}_q$.

donc $|\ker \Lambda| = \deg P = k$ donc $|H(q, k)| = \frac{q-1}{k}$.

Soit $H = H(q, k)$

Théorème 6

Soit $\psi \in \widehat{\mathbb{F}_q^\times / H}$, on définit

$$\begin{aligned} \tilde{\psi} : \mathbb{F}_q^\times &\longrightarrow \mathbb{F}_q^\times / H \longrightarrow \mathbb{C}^* \\ a &\longmapsto \psi(\bar{a}) \end{aligned}$$

Alors pour $\chi \in \widehat{\mathbb{F}_q}$,

$$\widehat{1}_H(\chi) = \frac{1}{k} \sum_{\psi \in \widehat{\mathbb{F}_q^\times / H}} G(\chi, \tilde{\psi})$$

Démonstration 6

On observe $\frac{1}{k} \sum_{\psi \in \widehat{\mathbb{F}_q^\times / H}} G(\chi, \tilde{\psi}) = \frac{1}{k} \sum_{a \in \mathbb{F}_q^\times} \chi(a) \sum_{\psi \in \widehat{\mathbb{F}_q^\times / H}} \tilde{\psi}(a) = \frac{1}{k} =$
 $\frac{1}{k} \sum_{a \in \mathbb{F}_q^\times} \chi(a) \sum_{\psi \in \widehat{\mathbb{F}_q^\times / H}} \psi(\bar{a}) = \sum_{a \in \mathbb{F}_q^\times} \chi(a) \delta_{\bar{1}, \bar{a}} k = \sum_{a \in H} \chi(a) = \widehat{1}_H(\chi)$

Conséquence + bilan

$$\text{Or } \phi(H) = \max_{\chi \in \widehat{\mathbb{F}_q} \setminus \{1\}} |\widehat{1}_H(\chi)|$$

Donc par inégalité triangulaire on en déduit $\phi(H) \leq \sqrt{q}$.

On a réussi à majorer ϕ !

Théorème 7

Supposons que $k|q-1$, alors

$$\left| \mathfrak{N}(q, k) - \frac{(q-1)^3}{qk^3} \right| < \sqrt{q} \frac{q-1}{k}$$

Démonstration 7

Suit du théorème 4 avec $A_1 = A_2 = A_3 = H(q, k)$ et $\phi(H(q, k)) \leq \sqrt{q}$

```
julia alt.jl

F(2^3), k=7 | -3.0 < 0.0 < 3.0
F(5^2), k=4 | -21.0 < 12.0 < 39.0
F(7^3), k=9 | -544.0 < 228.0 < 864.0
F(139^1), k=6 | -184.0 < 0.0 < 359.0
F(13^2), k=8 | -218.0 < 168.0 < 328.0
```

Figure: Exemple d'encadrements dans \mathbb{F}_8 , \mathbb{F}_{25} , \mathbb{F}_{343} , \mathbb{F}_{139} et \mathbb{F}_{169}

Démonstration 0 quand $k|q-1$

Supposons que $q \geq k^4 + 4$,

$$\frac{1}{q} \left(\frac{q-1}{k} \right)^3 \geq \sqrt{q} \frac{q-1}{k} \iff \frac{(q-1)^4}{q^3} \geq k^4 \iff q \left(1 - \frac{1}{q} \right)^4 \geq k^4$$

Or $\left(1 - \frac{1}{q} \right)^4 \geq 1 - \frac{4}{q}$ donc $q \left(1 - \frac{1}{q} \right)^4 \geq q - 4 \geq k^4$ donc $\mathfrak{N}(q, k) > 0$

Soit $k \geq 3$

Remarque

Il suit du théorème de Bezout que

$$H(q, k) = H(q, \text{pgcd}(q-1, k))$$

ce qui permet de se ramener au cas précédent.

Le théorème 0 est donc démontré !
